Abstract

The different schemes for the definition of the Z boson mass are analyzed. It is shown that the scheme, defining the mass as pole of the real part of the Z boson propagator and the width as the imaginary part of the propagator at the same point results in the gauge dependent results for these parameters in a two-loop approximation. On the other hand, the scheme, where the mass and width are related to the position of the pole of the propagator in the complex plane leads to the gauge independent result. It is argued that the gauge dependence of mass and width does not contradicts to the gauge invariance of the amplitude.

¹ The results were obtained at the High Energy Physics Institute of Tbilisi State University, Tbilisi, Georgia (March 1992).

1 Introduction

Recently the problem of the definition of Z boson mass and width has been discussed [1, 2]. The problem refers to the definition of the physical parameters of unstable particle. The Z boson's *in* and *out* states can not be considered as the eigenvectors of the energy-momentum operator (clearly this is true for any unstable system). Thus we have no unambiguous theoretical prescription for the definition of Z boson mass. The conventional way is to extract the mass and the width from the amplitudes of processes containing the corresponding resonance in the S -channel. E.g. the amplitude of the process $e^+e^- \rightarrow f\bar{f}$ near its peak position is often parameterized as [2, 3]:

$$A(S) = \frac{\mathcal{R}}{S - M_Z^2 + i\Gamma_Z M_Z} + r(S) \quad (1)$$

or

$$A(S) = \frac{\mathcal{R}}{S - (M_Z - i\Gamma_Z/2)^2} + r(S), \quad (2)$$

where $\mathcal{R}$ is the residue, the remainder, less singular part of the amplitude is designated by $r(S)$ and it is assumed that the first term numerically exceeds r . The parameterization (1)-(2) may be obtained from the conditions on the Green function of Z boson field. These conditions define the renormalization scheme, and as a consequence, the resonance parameters.

In consideration of the mass and width two schemes are prevalent.

In the framework of the first scheme the resonance parameters are defined as $M_Z^2 = \text{Re } S_p$, $M_Z\Gamma_Z = \text{Im } S_p$ [2], where S_p is the position of the pole of propagator in a complex S -plane [2]:

$$D^{-1}(S_p) = 0 \quad (3)$$

In (2) D^{-1} is the denominator of the exact propagator of the Z boson.

In the another, so called on mass-shell scheme, the variable S remains real and the definition is following [3]:

$$\text{Re } D^{-1}(M_Z^2) = 0, \quad M_Z\Gamma_Z = \text{Im } D^{-1}(M_Z^2) \quad (4)$$

Of course, many different schemes can be introduced. E.g. the mass can be defined as the peak position of the amplitude, but in this case it would depend on the process under consideration. From the theoretical point of view it is preferable that the mass of an unstable particle, in a full analogy with the case of stable one, is defined without referring to any particular element of the S matrix but the propagator. The condition imposed on the propagator of an unstable particle is a realization of the scheme defining mass and width.

In this paper we investigate the gauge dependence of the resonance parameters, defined in schemes (3) and (4). Note, that the gauge independence of the physical mass and width is the separate requirement, not being the direct consequence of the

gauge independence of amplitude (1)-(2). In other words, from the requirement of gauge independence of observables (in our case - Z line shape) it does not follow necessarily that the resonance parameters should be gauge invariant. In discussing the gauge dependence one expects that since the pole of the amplitude is a physical quantity, the mass and the width, defined through scheme (3) are gauge independent, while it is not evident in case of scheme (4). Below we check this argument in the framework of perturbation theory.

In section 2 we demonstrate that M_Z and Γ_Z , defined in scheme (3), are gauge independent in the two-loop approximation while the scheme (4) leads to the gauge dependence of these parameters (from [2] we have learned that A. Sirlin has arrived to the same conclusion about the scheme (4). Unfortunately at the present time the publication [4] is not available to us and hence we are not able to compare our arguments).

In section 3 it is argued that if we use the scheme (4) or any other scheme with the gauge dependent M_Z and Γ_Z , the scattering amplitude is still gauge independent.

We use the bare Lagrangian in which the Higgs field condensate v and the ZA mixing are chosen in the tree approximation [3]. The input parameters are the bare electromagnetic charge e_0 and the bare masses M_{0i} . Calculations are performed in R_ξ gauge in the framework of dimensional regularization. We use Feynmann rules from the review [3].

2 Two-loop Analysis of Gauge Dependence

To investigate the gauge dependence of M_Z and Γ_Z defined in the scheme (3) let us express S_P as follows:

$$S_P = M_{0Z}^2 + e_0^2 \delta M_1^2 + e_0^4 \delta M_2^2 + \dots, \quad (5)$$

where the complex numbers δM_i do not depend on e_0 .

It is straightforward to show that the contributions from terms with the gauge parameters α_W , α_Z and α_A are factorized in the expression for δM_1^2 . The most time-taking part of calculations in R_ξ gauge is that with the gauge parameter α_W [3]. Therefore, in the two-loop approximation where there is no factorization we will investigate only the sector with α_W to which we refer throughout this paper as α .

This parameter appears in the free propagators of W , χ and c (for the denotions see [3]; χ and c correspond to the pseudogoldstone and ghost degrees of freedom appearing in R_ξ gauge):

$$D_W^{\mu\nu}(p) = \frac{1}{p^2 - M_{0W}^2} \left(g^{\mu\nu} - \frac{p^\mu p^\nu}{M_{0W}^2} \right) + \frac{p^\mu p^\nu}{M_{0W}^2 (p^2 - \alpha M_{0W}^2)} \quad (6)$$

and

$$D_\chi(p) = -\frac{1}{p^2 - \alpha M_{0W}^2}, \quad D_{c^\pm}(p) = -\frac{1}{p^2 - \alpha M_{0W}^2} \quad (7)$$

For brevity we will term the denominators with α as α -terms.

One loop correction to the Z boson self energy contains terms, linear in α (i.e. integrand contains only one α -denominator) as well as α^2 -terms (the product of two α -denominators). Two loop correction contains α , α^2 and α^k , $k > 2$ terms. The simple calculation based on Ward identities demonstrates that α^k , $k > 2$ terms cancel trivially, and the technique is exactly the same as in the case of stable particles. Further we will discuss only α and α^2 -terms which are present in one-loop and two-loop corrections and interfere with each other.

The α^2 -terms appear only in the diagram Fig.1,a) and all the diagrams contain

Figure 1: One loop contribution from the " α - sector" in Z boson self energy.

terms, linear in α . Even now two-loop calculations are still tedious.

To proceed further let us note that in the sense of the gauge dependence the crucial difference between the results following from the schemes (3) and (4) is caused by fermion loops, leading to $Im \delta M_1^2 \neq 0$. Since our goal is to establish the (possible) gauge dependence of M_Z and Γ_Z , in the gauge independent part of δM_1^2 we retain the contribution from the lepton sector only. The quark loop contribution gives the similar result.

Summarizing, we consider only α and α^2 terms from the " α -sector" and in the expression for δM_1^2 only the contributions from the electron and neutrino loops are taken into account.

After these introductory remarks we are in a position to discuss the gauge dependence of M_Z and Γ_Z .

Let us consider first the one-loop contribution to $\Pi_{\mu\rho}$ - self energy of the Z boson. To extract parameters M_Z and Γ_Z it is enough to consider the coefficient of $g_{\mu\rho}$. Therefore we will follow only the integrals, leading to this tensor structure. The corresponding contribution of α and α^2 terms in $\Pi_{\mu\rho}$ is:

$$\Pi_{\mu\rho}(p, \alpha) = -e_0^2 \frac{(p^2 - M_{0Z}^2)(p^2 + M_{0Z}^2)}{M_{0W}^2(M_{0Z}^2 - M_{0W}^2)} J_{1\mu\rho} -$$

$$e_0^2 g_{\mu\rho} \left[2 \frac{M_{0Z}^2 - p^2}{M_{0Z}^2 - M_{0W}^2} J_1 + 4(M_{0Z}^2 - p^2) J_2 \right] - e_0^2 \frac{4(M_{0Z}^2 - p^2)}{M_{0W}^2} J_{2\mu\rho}, \quad (8)$$

where p is the Z boson momentum and

$$J_{1\mu\rho} = i \int d^n q \frac{q_\mu q_\rho}{(q^2 - \alpha M_{0W}^2)((p+q)^2 - \alpha M_{0W}^2)}, \quad (9)$$

$$J_{2\mu\rho} = i \int d^n q \frac{q_\mu q_\rho}{(q^2 - M_{0W}^2)((p+q)^2 - \alpha M_{0W}^2)}, \quad (10)$$

$$J_1 = i \int d^n \frac{1}{q^2 - \alpha M_{0W}^2}, \quad (11)$$

$$J_2 = i \int d^n q \frac{1}{(q^2 - M_{0W}^2)((p+q)^2 - \alpha M_{0W}^2)} \quad (12)$$

In (9)-(12) n is a space-time dimension. In the one-loop approximation $\Pi_{\mu\rho}$ can be expressed as

$$\Pi_{\mu\rho} = g_{\mu\rho}(p^2 - M_{0Z}^2) - e_0^2 \left[\Pi_{\mu\rho}^{(1)inv}(p^2) + \Pi_{\mu\rho}(\alpha) \right], \quad (13)$$

where $\Pi_{\mu\rho}^{(1)inv} = g_{\mu\rho} \Pi^{(1)inv}$ and $\Pi_{\mu\rho}(\alpha)$ are correspondingly gauge independent and gauge dependent parts. The gauge independence of M_Z and Γ_Z in one-loop approximation is evident in both schemes, since in the scheme (3), where $p^2 = S_p$ we have

$$S_P - M_{0Z}^2 = e_0^2 \Pi^{(1)inv}(M_{0Z}^2), \quad (14)$$

and in the scheme (4) where $p^2 = M_Z^2$, we obtain:

$$\begin{aligned} M_Z^2 - M_{0Z}^2 &= e_0^2 Re \Pi^{(1)inv}(M_{0Z}^2), \\ M_Z \Gamma_Z &= e_0^2 Im \Pi^{(1)inv}(M_{0Z}^2) \end{aligned} \quad (15)$$

Let us proceed to the order e_0^4 . The self energy in the scheme (3) can be expressed as

$$\Pi_{\mu\rho}(S_P, \alpha) = -e_0^4 \left(\Pi^{(1)inv}(M_{0Z}^2) \right)^2 I_{\mu\rho} + O(e_0^6), \quad (16)$$

where

$$\begin{aligned} I_{\mu\rho} &= \frac{2M_{0Z}^2}{M_{0W}^2(M_{0Z}^2 - M_{0W}^2)} J_{1\mu\rho} - \\ &g_{\mu\rho} \left(\frac{2}{M_{0Z}^2 - M_{0W}^2} J_1 + 4J_2 \right) - \frac{4}{M_{0W}^2} J_{2\mu\rho} \end{aligned} \quad (17)$$

and in the scheme (4) $Re \Pi_{\mu\rho}$ can be expressed as

$$Re \Pi_{\mu\rho}(\alpha, p^2)|_{p^2=M_Z^2} = -e_0^4 Re \Pi^{(1)inv} Re I_{\mu\rho} \quad (18)$$

Figure 2: Two-loop contribution from "α - sector" in Z boson self energy.

Let us remind that in $\Pi_{\mu\rho}^{(1)inv}$ we consider contributions only from the electron and neutrino. Then, to investigate the gauge dependence in order e_0^4 it is necessary to consider the two-loop diagrams, Fig. 2 a) and b):

The contribution from α^2 -terms in $\Pi_{\mu\rho}$ from the diagram Fig. 2 a) at $p^2 = M_{0Z}^2$ is equal to:

$$-ie_0^4 \frac{M_{0Z}^4}{4M_{0W}^4(M_{0Z}^2 - M_{0W}^2)} J_{1\mu\sigma} \int d^n q \operatorname{tr} \left[G(p+q) \Gamma_\sigma G(q) \gamma_\rho \right], \quad (19)$$

where $G(p) = 1/(m_0 - \hat{p})$ is the free electron propagator and

$$\Gamma_\sigma = \gamma_\sigma \left[-1 + 4 \frac{M_{0Z}^2 - M_{0W}^2}{M_{0Z}^2} + \gamma_5 \right] \quad (20)$$

is the Ze^+e^- vertex. Let us discuss the cancelation technique for the terms similar to (19) for the diagram Fig. 2 b), containing two W bosons. First of all, we consider the fermion loop contribution multiplied on virtual W boson's momenta that correspond to α^2 -terms:

$$\int \frac{d^n k d^n q}{(k^2 - \alpha M_{0W}^2)((p+k)^2 - \alpha M_{0W}^2)} \Gamma_{\sigma\beta\rho}(-k, p+k, -p) \operatorname{tr} \left[G(p+q) \Gamma_\mu G(q) \hat{k} (1 - \gamma_5) S(q-k) (\hat{p} + \hat{k}) \right], \quad (21)$$

where $\Gamma_{\sigma\beta\rho}$ is the ZW^+W^- vertex and $S(p) = -1/\hat{p}$ is the free neutrino propagator. Using $\hat{k} = m_0 - G^{-1}(q) + S^{-1}(q-k)$ and $\hat{p} + \hat{k} = m_0 - G^{-1}(p+q) + S^{-1}(q-k)$ for

the trace in (19) we obtain:

$$\begin{aligned} tr \Big[& G(p+q)\Gamma_\mu G(q)(1+\gamma_5)(\hat{p}+\hat{k}) + m_0^2 G(p+q)\Gamma_\mu G(q)(1-\gamma_5)S(q-k) + \\ & m_0 G(p+q)\Gamma_\mu G(q)(1-\gamma_5) - m_0 G(p+q)\Gamma_\mu(1-\gamma_5)S(q-k) - \\ & m_0 \Gamma_\mu G(q)(1-\gamma_5)S(q-k) \Big] \end{aligned} \quad (22)$$

The terms with the three fermion propagators are canceled at $p^2 = M_{0Z}^2$ in the sum of all the diagrams of type Fig. 2 b). Without this cancelation the gauge dependence of M_z and Γ_Z is unavoidable. The terms in (22), containing the product of propagators G and S are canceled by the α^2 -terms, originated from the diagram Fig. 2 c). Now, the sum of diagrams Fig. 2 a) and b) is

$$ie_0^4 \frac{M_{0Z}^6 J_{1\rho\sigma}}{16M_{0W}^2(M_{0Z}^2 - M_{0W}^2)} \int d^n q \, tr \Big[G(p+q)\Gamma_\mu G(q)\Gamma_\sigma + S(p+q)\gamma_\mu(1-\gamma_5)S(q)\gamma_\rho(1-\gamma_5) \Big] \quad (23)$$

It is straightforward to demonstrate that the terms in (23), leading to the tensor structure $g_{\mu\rho}$ can be expressed as:

$$e_0^4 \frac{2M_{0Z}^2}{M_{0W}^2(M_{0Z}^2 - M_{0W}^2)} \left[\Pi_{(e)}^{(1)inv}(M_{0Z}^2) + \Pi_{(\nu)}^{(1)inv}(M_{0Z}^2) \right] J_{1\mu\rho}, \quad (24)$$

where $\Pi_{(e)}^{(1)inv}$ and $\Pi_{(\nu)}^{(1)inv}$ refer to contributions of electron and neutrino. The α -terms is canceled in the sum of the expressions (16) and (24), and it turns out that S_p is gauge invariant in order of e_0^4 . On the other hand, the sum of the real parts of (18) and (23) still depends on α . Therefore, the scheme (3), in distinct with (4), defines the gauge independent parameters M_Z and Γ_Z .

We have checked the gauge independence of S_p also in the framework of conventional covariant gauge, when the gauge fixing term is $\partial_\mu W_\mu^2/2\alpha$. In this case the diagrams type of Fig. 1 b) and c) are gauge independent. The cancelation of the gauge dependent terms occurs in a full analogy with the case of R_ξ gauge.

A few words about ZA mixing: when we define the mixing scheme by the requirement that Green's function $\langle ZA \rangle$ has no poles (i.e. the mass-shell for the photon is defined only from $\langle AA \rangle$ and S_p is defined only from $\langle ZZ \rangle$), there arise a new effective vertices but S_p does not change. Note that the same value of this parameter is obtained as a position of pole of the Green's functions $\langle aa \rangle$, $\langle B_3 B_3 \rangle$ and $\langle a B_3 \rangle$, where a and B_3 are the original gauge fields of the gauge groups $U(1)$ and $SU(2)$ leading after mixing to A and Z .

Note also that if we take into account the quantum corrections in the definition of the Higgs condensate in the bare Lagrangian, i.e. $v = v_0 + \delta v$, then $\langle \phi \rangle = 0$, but the parameter S_p would be the same. Moreover, the replacement $v_0 \rightarrow v$ does not affect the Green's function which does not contain the Higgs field ϕ on external lines.

3 Gauge dependence of M_Z and Γ_Z and the Gauge Invariance of the Amplitude

As we have demonstrated in section 2, the parameters M_Z and Γ_Z defined in scheme (3) do not depend on the gauge parameter in the two-loop approximation. Since the parameters M_Z and Γ_Z defined in the scheme (4) are gauge dependent, it might seem that the scheme (3) is preferable. Below we show that the requirement of the gauge independence as well as the requirement of numerical convergence does not lead in principle to the preference of one particular scheme.

Let us express M_Z and Γ_Z in the framework of regularized theory (i.e. $n \neq 4$) as follows:

$$M_Z = M_{0Z} \sum_{k=1}^{\infty} e_0^{2k} \delta_{1k}, \quad \Gamma_Z = e_0^2 M_Z^{n-3} \sum_{k=1}^{\infty} e_0^{2k} \delta_{2k} \quad (25)$$

It is possible to resolve M_{0Z} and e_0^2 in terms of M_Z and Γ_Z :

$$M_{0Z} = M_Z \sum_{k=1}^{\infty} \left(\frac{\Gamma_Z}{M_Z} \right)^k \Delta_{1k} = M_Z Z_{M_Z}, \quad (26)$$

and

$$e_0^2 = \frac{\Gamma_Z}{M_Z^{n-3}} \sum_{k=1}^{\infty} \left(\frac{\Gamma_Z}{M_Z} \right)^k \Delta_{2k} = \Gamma_Z Z_{\Gamma_Z}, \quad (27)$$

where Z_{M_Z} and Z_{Γ_Z} are the mass and width renormalization factors.

Clearly, the coefficients in expressions (25) - (27) are gauge independent when calculated in the scheme (3) and depend on a gauge in the case of scheme (4).

If we substitute (26)-(27) in the expression for the physical quantity, e.g. the amplitude $\langle e^+ e^- | f \bar{f} \rangle$ we obtain the ultraviolet finite result which may be parameterized as (1)-(2), or as follows:

$$A(S) = \sum_{k=1}^{\infty} \left(\frac{\Gamma_Z}{M_Z} \right)^k a_k(S) \quad (28)$$

The gauge independence of $A(S)$ in a scheme (3) is evident since the coefficients $a_k(S)$ do not depend on gauge parameters. In scheme (4) the coefficients $a_k(S)$ contain α explicitly but this does not lead to the gauge dependence of amplitude $A(S)$. Indeed, for this case, in the expression

$$\frac{dA}{d\alpha} = \frac{\partial A}{\partial \alpha} + \frac{\partial A}{\partial \Gamma_Z} \frac{d\Gamma_Z}{d\alpha} + \frac{\partial A}{\partial M_Z} \frac{dM_Z}{d\alpha} \quad (29)$$

every term is non vanishing but in the sum they cancel since the scheme (4) is connected with the scheme (3) via the renormalization group equations with respect to the parameter α . These equations can be obtained from (26)-(27):

$$\frac{dM_Z}{d\alpha} = \beta_{M_Z} M_Z, \quad \frac{d\Gamma_Z}{d\alpha} = \beta_{\Gamma_Z} \Gamma_Z, \quad (30)$$

where

$$Z_{M_Z}\beta_{M_Z} \equiv -\frac{dZ_{M_Z}}{d\alpha}, \quad Z_{\Gamma_Z}\beta_{\Gamma_Z} \equiv -\frac{dZ_{\Gamma_Z}}{d\alpha} \quad (31)$$

The similar equations for the other masses M_i can be easily obtained. It is evident that if we consider the scheme where $\beta_{M,\Gamma} \neq 0$, the independence of physical quantities on α appears in a full analogy with the independence on a renormalization point. If we use (29) and (30), we would obtain from (28) that

$$\frac{d}{d\alpha} \sum_{k=1}^N \left(\frac{\Gamma_Z}{M_Z} \right)^k a_k(S) = O \left[\left(\frac{\Gamma_Z}{M_Z} \right)^{N+1} \right] \quad (32)$$

in each order of Γ_Z . Clearly, the same relations hold for the remaining gauge parameters. Relation similar to (32) with respect to renormalization point μ states that (see, e.g. [5]):

$$\frac{dP_N(\mu, g(\mu))}{d\mu} \equiv \frac{d}{d\mu} \sum_{k=1}^N g^k(\mu) P_k = O \left(g(\mu)^{N+1} \right), \quad (33)$$

where P_N is a physical quantity calculated up to order N -th order in renormalized coupling $g(\mu)$. In any particular order of perturbation theory the response of a physical quantity on $\mu \rightarrow \mu + d\mu$ is of a *next order* in $g(\mu)$. Evidently, the exact expression is the renormalization point (and gauge parameter) independent. So, the requirement of the gauge independence of the amplitude $\langle e^+e^- | f\bar{f} \rangle$ is not sufficient to prefer scheme (3).

Let us consider the problem of numerical analysis. The peak position of the amplitude, S_0 , is defined as the solution of the equation:

$$\frac{d}{dS} | A(S) | = 0 \quad (34)$$

It is easy to show that in a scheme (3) we obtain

$$S_0 = M_Z^2 + \frac{\Gamma_Z^3}{M_Z^3} \sum_{k=0}^{\infty} \left(\frac{\Gamma_Z}{M_Z} \right)^k C_k(M_i), \quad (35)$$

while the scheme (4) leads to

$$S_0 = M_Z^2 + \frac{\Gamma_Z^2}{M_Z^2} \sum_{k=0}^{\infty} \left(\frac{\Gamma_Z}{M_Z} \right)^k C_k^*(M_i) \quad (36)$$

Evidently, if the series (35) and (36) converge fast enough, the scheme (3) is preferable when $\Gamma_Z \ll M_Z$. But from the theoretical point of view this is rather troublesome to confirm. Indeed, the coefficient functions C_k and C_k^* depend on the masses of all the particles of the standard model, so their values can not be estimated with the help of the current data.

Note that there exists other scheme which leads to the same results in a two-loop approximation as the scheme (3). For example one can define a new scheme by the relation:

$$\frac{d}{dS} | D^{-1}(S) |_{S=M_Z^2} = 0 \quad (37)$$

The simple calculation shows that M_Z , defined by (37) differs from the result of scheme (3) only in order e_0^6 . In other words, in a two-loop approximation the scheme (37) leads to the gauge independent M_Z and this M_Z satisfies relation, similar to (3). The results following from these two schemes differ only in three-loop approximation.

4 Discussion

In this paper, based on the gauge independence and numerical analysis we have investigated the schemes defining the mass and the width of Z boson.

The relations (35) and (36) demonstrate that the schemes (3) and (37) may be preferable. On the other hand, since in a scheme (4) the arbitrary parameter α remains, the problem of convergence in (36) requires the consideration of the renormalization group equations (30). It may occur that for some numerical values of α the series (36) would converge faster than the series (35). It is not surprising since from (29)-(30) it is evident that the gauge parameter α plays the role, analogous of renormalization point and thus, in principle, the variation of α can improve the convergence of series in Γ_Z/M_Z . Hence, the requirement of the numerical convergence can not be used in defining the physical mass and the width of the Z boson, since this requirement may be in contradiction with requirement of gauge invariance of these parameters. Note also that the result of numerical analysis depends essentially on the process under consideration.

From the requirement of gauge independence the schemes (3) and (37) are preferable. Unfortunately, this principle is necessary but not sufficient and therefore does not leads to the unique choice of a scheme. Indeed, besides (3) and (37), infinitely many schemes for defining the gauge independent parameters can be pointed out. For example let us express the Z boson propagator as

$$D = D^{inv} + D^*, \quad (38)$$

where D^{inv} stands for the contribution of physical degrees of freedom (i.e. D^{inv} is gauge independent) and D^* varies from gauge to gauge. Consider now any conditions on real and imaginary parts of D^{inv} , leading to the ultraviolet renormalization. It is evident that these conditions define two gauge invariant parameters which may be treated as M_Z and Γ_Z .

Despite of this non uniqueness, the schemes (3) and (37) are remarkable. Indeed, M_Z and Γ_Z defined in scheme (3) are connected with the position of the pole of propagator on the complex plane and in scheme (37) they can be obtained from the

position of the peak of amplitude on real axis. Apparently it is the scheme (3) that defines the physical mass and the width of Z boson, since, from our point of view, only this scheme allows us to formulate the Lehmann-Symanzik-Zimmermann (LSZ) reduction technique [5] for the processes involving Z boson in initial or final states.

Some papers contain attempts to generalize LSZ technique for unstable particles (see e.g [6]) but we think that more thoroughful analysis is necessary. Our recent calculations show that the residue of the amplitude $\langle e^+e^-|f\bar{f}\rangle$ in a two-loop approximation is gauge independent at $S = S_p$. This fact already indicates the incontrovertible preference of scheme (3) since the gauge independence of the residue apparently leads to the gauge independent amplitude for the decay $Z \rightarrow f\bar{f}$.
